Most of the rock is slightly vesicular, but it has no strongly developed flow structure. One thin section appears to be a leucotrachyte, containing mainly sanidine and a considerable amount of hematite and some quartz. No mafic minerals are present. **BASALT FLOWS** Basic volcanic rocks appear in two rather widely separated areas. They underlie the flat-topped hills, which are known as Las Mesas, at the western end of the Sierra de Santa Rosa, and they form a range of low but rather conspicuous hills in the Bonanza valley northeast of Terminal. In both localities a series of basalt flows overlie loosely consolidated arkose, which may be a reworked volcanic ash. In the Las Mesas area the volcanic rocks have a maximum exposed thickness of more than 200 meters and dip to the west at an angle of about 5. There is no evidence of faulting in the area, and the dip probably represents an original slope. The arkosic sediments are covered by talus from the overlying flows and are rarely exposed. Those which were seen are light-gray to reddish or yellowish crumbly poorly cemented rocks, and only two specimens were examined petrographically. One was found to be composed of rounded grains of plagioclase, quartz, and chalcedony, and rounded rock fragments in a chalcedonic cement. The rock fragments consist of basalt or basalt and chalcedony. The other rock is a well-sorted loosely consolidated sand containing angular to moderately rounded grains...
